## Exercise 2.1-3 Linear Search

```
1: procedure LINEAR-SEARCH( $A, v$ )
2:   for  $i \leftarrow 1$  to  $\text{length}[A]$  do
3:     if  $A[i] == v$  then
4:       return  $i$ 
5:   return NILL
```

**Proof of correctness** To prove linear search is correct, I formulate a *loop invariant* that need to hold true at *initialization*, during *maintainance* and at *termination*.

**Loop invariant** At the start of loop iteration  $i$ , the value  $v$  is not in the sub-array  $A[1..i-1]$ . In formal terms,  $v \notin \{A[j] | j \in \{1, \dots, i-1\}\}$

**Initialization** At initialization  $i = 0$ , so the sub-array  $A[1..i-1]$  is empty. So  $v$  is trivially not a member of that array, and the loop invariant holds.

**Maintenance** Assuming that  $v$  is not in the sub-array  $A[1..i-1]$  at the start of iteration  $i$ , then two outcomes are possible during the iteration. Either,  $A[i] == v$  and the loop terminates, or  $A[i] \neq v$  and  $v$  is not an element of the array  $A[1..i]$  which is the loop invariance condition for iteration  $i+1$ .

**Termination** The algorithm terminates in two different ways. The first happens when  $A[i] == v$ , assuming  $v \notin A[1..i-1]$  before termination, then the loop invariant still holds. Again, assuming  $v \notin A[1..i-1]$  before termination. In the second case we have that  $i = n+1$ , in that case  $v \notin A[1..i-1] = A[1..n]$ , which is the entire array, and the procedure returns NILL.

## 2.2-3 Running time of Linear search

Assuming the index of correct element is uniformly distributed from 1 to  $n$ , the expected index is  $E[i] = n/2$ . So the average case running time must be  $c_1 \frac{n}{2} + c_2$ , where  $c_1$  is the running time of each comparison  $A[i] == v$  and the loop increment, and  $c_2$  is the running time of the return statement. In the worst case

the algorithm needs to run through all  $n$  elements as well as returning NIL, so the running time is  $c_1n + c_2$ . Both the average and worst case running times of linear search are  $\Theta(n)$ .

### Exercise 2.3-3 Linear Recurrence

To show that the recursion

$$T(n) = \begin{cases} 2 & \text{if } n = 2 \\ 2T(n/2) + n & \text{if } n = 2^k, \text{ for } k > 1 \end{cases}$$

is  $T(n) = n \lg n$ . Assuming that  $n$  is a power of two we have  $n = 2^k$  for  $k \in 1, 2, \dots$ . For  $k = 1$  we have that  $T(n) = T(2) = 2$  by definition of  $T$ .

$$2 \lg(2) = 2 = T(2).$$

Hence the claim holds for  $k = 1$ .

Next, assuming that  $T(2^{k-1}) = 2^{k-1} \lg 2^{k-1} = (k-1)2^{k-1}$  we have that,

$$\begin{aligned} T(n) &= 2T(n/2) + n \\ &= 2T(2^k/2) + 2^k \\ &= 2T(2^{k-1}) + 2^k \\ &= 2((k-1)2^{k-1}) + 2^k \\ &= k2^k \\ &= 2^k \lg(2^k) = n \lg n \end{aligned}$$

so the claim also holds for  $k$  given it holds for  $k-1$ , at since it holds true for  $k=1$  it holds for any  $k \geq 1$ .  $\square$

### Exercise 2.3-5 Binary search

```

1: procedure BINARY-SEARCH(A, p, r, v)
2:   if  $p \leq r$  then
3:      $m = p + \lfloor \frac{r-p}{2} \rfloor$ 
4:     if  $A[m] == v$  then
5:       return m
6:     else if  $A[m] > v$  then
7:       return BINARY-SEARCH(A, p, m - 1, v)
8:     else if  $A[m] < v$  then
9:       return BINARY-SEARCH(A, m + 1, r, v)
10:  return NIL
```

In the worst case, binary search needs to split the array in two, until the last split goes from two elements to a single one. A way of assessing the running time is to understand how many possible splits can be made. Assuming the length of the array is  $n = 2^k$ , the length after the first split is simply  $n/2$ . Finding

the length of the consequent halved arrays, amounts to raising the *half* to the number of splits and multiplying by the initial size,  $n$ . So, to find the number of splits which result in the length of 1, we need to solve the following,

$$1 = \frac{n}{2^x} \Leftrightarrow 2^x = n \Leftrightarrow x = \lg n.$$

So we can conclude, that the recursion calls itself at most  $\lg n$  times, this is an indication of the worst case running time being  $\Theta(\lg n)$ .

### Problem 2-3 Horner's rule

**a. Running time** The running time of each line in Horner's algorithm is given by,

- 1:  $y \leftarrow 0$  ▷ Running time:  $c_1$
- 2:  $i \leftarrow n$  ▷ Running time:  $c_1$
- 3: **while**  $i \geq 0$  **do** ▷ Running time:  $c_2$  repeated  $n + 2$  times.
- 4:      $y \leftarrow a_i + x \cdot y$  ▷ Running time:  $c_1 + c_+ + c_\bullet$  repeated  $n + 1$  times.
- 5:      $i \leftarrow i - 1$  ▷ Running time:  $c_1 + c_-$  repeated  $n + 1$  times.

The total running time is  $T(n) = 2c_1 + c_2(n + 2) + (2c_1 + c_+ + c_\bullet + c_-)(n + 1)$ , that is

$$T(n) = C_1 + C_2n$$

with  $C_1 = 4c_1 + 2c_2 + c_+ + c_\bullet + c_-$  and  $C_2 = 2c_1 + c_2 + c_+ + c_\bullet + c_-$ . So, it's clear that  $T(n)$  is a linear function of  $n$  so  $T(n) = \Theta(n)$ .

### b. Naive polynomial evaluation

- 1:  $y \leftarrow 0$
- 2:  $z \leftarrow 1$
- 3:  $i \leftarrow 0$
- 4:  $j \leftarrow 0$
- 5: **while**  $i \leq n$  **do**
- 6:     **while**  $j < i$  **do** ▷ This inner loop is evaluated  $\sum_{k=1}^{n+1} k$  times.
- 7:          $z \leftarrow z \cdot x$
- 8:          $j \leftarrow j + 1$
- 9:      $y \leftarrow y + a_i \cdot z$
- 10:     $i \leftarrow i + 1$
- 11:     $z \leftarrow 1$
- 12:     $j \leftarrow 0$

The inner loop is called  $\sum_{k=1}^{n+1} k = (n + 1)(n + 2)/2 = n^2 + 3n + 2$  times, and the evaluation in the outer loop are called  $n$  times, so the running time is no more than,

$$T(n) = C_0 + C_1n + C_2n^2$$

for the appropriate constants. So for the naive implementation  $T(n) = \Theta(n^2)$ .

**c. Proof of correctness** Considering the loop invariant,

$$y = \sum_{k=0}^{n-(i+1)} a_{k+i+1} x^k.$$

**Initialization** We have  $i = n$  so the above expression is  $y = \sum_{k=0}^{-1} a_{k+n+1} x^k = 0$ , which is in line with the assigned value to  $y$  of 0 in line 1 of the algorithm. So the loop invariant is true at initialization.

**Maintainance** During maintenance assuming  $i = j + 1$  with  $0 \leq j + 1 < n$  and ssuming  $y$  is given by

$$y = \sum_{k=0}^{n-(j+2)} a_{k+j+2} x^k = a_{j+2} + a_{j+3}x + a_{j+4}x^2 + \dots + a_n x^{n-(j+2)}$$

at the start of the loop, then at the start of the next iteration,  $i = j$ ,  $y$  is given by

$$\begin{aligned} y &\leftarrow a_{j+1} + x \cdot y \\ &= a_{j+1} + x \left( a_{j+2} + a_{j+3}x + a_{j+4}x^2 + \dots + a_n x^{n-(j+2)} \right) \\ &= a_{j+1} + a_{j+2}x + a_{j+3}x^2 + a_{j+4}x^3 + \dots + a_n x^{n-(j+1)} \end{aligned}$$

which corresponds to the loop invariant at iteration  $i = j$ . So, the loop invariant holds in the maintainance step as well.

**Termination** At termination  $i = -1$  so the loop invariant becomes the full polynomial,

$$y = \sum_{k=0}^n a_k x^k = a_0 + a_1x + a_2x^2 + \dots + a_n x^n.$$

Assuming the invariant holds true at the start of the iteration, the algorithm evaluates  $y$  to the correct value.

**d. Conclusion** In conclusion, the loop invariant holds true at initialization, through maintainance all the way to termination by induction, and ends with a correct evaluation of the polynomial, so we can conclude that the algorithm is correct.
